

DIAMONDS

These crystals known as Pecos Valley Diamonds (SiO_2) are only found in an area 100 miles long and 20 miles wide, along the Pecos River near Roswell, New Mexico. These crystals were formed 300 million years ago during the Permian time of the Paleozoic era. Evaporation of the Permian sea left gypsum beds. Years of erosion have exposed these quartz crystals which were formed in the gypsum beds. These crystals occur as double terminated hexagonal prisms. They vary from colorless to shades of white, orange, red, brown, and black.

The "diamonds" were first recorded in 1583 by Don Antonio de Espejo, a Spanish explorer. It is known that they were used as drills by the early cliff dwellers of the Southwest region. Later day Indians used them as ceremonial tools and for jewelry.
